  - 2.5 Laplacian Eigenmaps
  - 2.6 Vector Field based Dimensionality Reduction
- 3. Manifold Regularization: Semi-Supervised Setting

- The data space may not be a Euclidean space, but a nonlinear manifold
- Unfold a manifold, and preserve the geometry structure.
- Euclidean distance ⇒ geodesic distance

Find a Euclidean embedding, and then perform traditional learning algorithms in the Euclidean space.

#### **Definition of Manifold Learning**

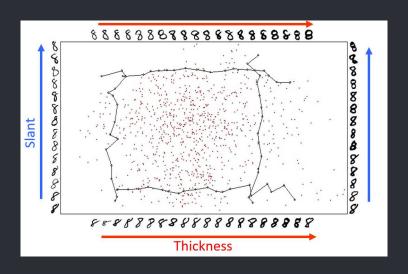

Given data points  $\mathbf{x}_1, \dots, \mathbf{x}_m \in \mathcal{M} \subset \mathbb{R}^n$ , try to find a map  $f : \mathcal{M} \to \mathbb{R}^d$ ,  $d \ll n$ , where  $f = (f_1, \dots, f_d)$ ,  $f_i : \mathcal{M} \to \mathbb{R}$ 

- The manifold is unknown! We have only samples!
- How to compute the distance on M?
- How to find the mapping function f

## Manifold of Face Images

#### Manifold of Handwritten Digits

- 1. Manifold
- Manifold based Dimensionality Reduction
  - 2.1 Principal Component Analysis
  - 2.2 Multidimensional scaling
  - 2.3 ISOMAP
  - 2.4 Local Linear Embedding
  - 2.5 Laplacian Eigenmaps
  - 2.6 Vector Field based Dimensionality Reduction
- 3. Manifold Regularization: Semi-Supervised Setting

#### PCA: Traditional Dimensionality Reduction Method

Principal Component Analysis using linear projection to project data to some directions which have maximum variances

$$\mathbf{p}_{opt} = \arg \max_{\mathbf{p}} \sum_{i=1}^{m} (y_i - \bar{y})^2$$
$$= \arg \max_{\mathbf{p}} \mathbf{p}^T C \mathbf{p}$$
$$s.t. \mathbf{p}^T \mathbf{p} = 1$$

- If the manifold is linear, PCA can find the optimal result
- PCA can not process nonlinear manifold

#### MDS and ISOMAP

Multidimensional scaling tries to preserve the Euclidean distances

$$\Delta := \begin{pmatrix} \delta_{1,1} & \delta_{1,2} & \dots & \delta_{1,m} \\ \delta_{2,1} & \delta_{2,2} & \dots & \delta_{2,m} \\ \vdots & \vdots & & \vdots \\ \delta_{m,1} & \delta_{m,2} & \dots & \delta m, m \end{pmatrix}$$

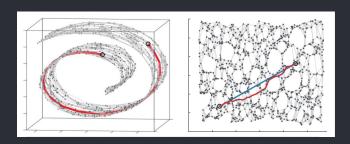

The  $\delta$  is the Euclidean distance of every two points  $\delta_{ij} = \|\mathbf{x}_i - \mathbf{x}_j\|$ 

$$\min_{\mathbf{y}_1,...,\mathbf{y}_m} \sum_{i < j} (\|\mathbf{y}_i - \mathbf{y}_j\| - \delta_{i,j})^2, \quad \dim(\mathbf{y}_i) \ll \dim(\mathbf{x}_i)$$

#### MDS and ISOMAP

**ISOMAP** tries to keep the geodesic distances instead of the Euclidean distances.

- How to evaluate the geodesic distances with limited samples?
- Construct the adjacency Graph, and calculate the shortest distances (Dijstra or Floyd algorithm)

#### **Local Linear Embedding**

Local Linear Embedding(2000 Science) is another famous manifold learning method. It tries to preserve the local linear relationship.

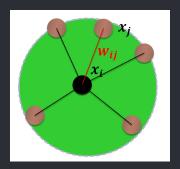

$$\min \epsilon(W) = \min \sum_{i} ||\mathbf{x}_{i} - \sum_{j} W_{ij} \mathbf{x}_{j}||$$

$$s.t. \sum_{i} W_{ij} = 1$$

#### **Local Linear Embedding**

Local Linear Embedding(2000 Science) is another famous manifold learning method. It tries to preserve the local linear relationship.

$$\min \Phi(\mathbf{y}) = \min \sum_{i} ||\mathbf{y}_{i} - \sum_{i} W_{ij} \mathbf{y}_{j}||^{2}$$

#### Laplacian Eigenmaps

In Laplacian Eigenmaps, a conclusion has been proofed:

$$|f(z) - f(x)| < ||\nabla f(x)|| \cdot ||z - x|| + o(||z - x||)$$

 If x<sub>i</sub> and x<sub>j</sub> are close to each other and the gradient of map f is small, we can sure that f(x<sub>i</sub>) and f(x<sub>j</sub>) preserve local structure.

Construct Laplace matrix and get object function

$$\min_{\|f\|_{L^2(\mathcal{M})}=1} \int_{\mathcal{M}} \|\nabla f(\mathbf{x})\|^2 \Rightarrow \min_{j,j} \sum_{i,j} (y_i - y_j)^2 W_{ij} \Rightarrow L\mathbf{y} = \lambda D\mathbf{y}$$

#### **Laplace Operator on Graph**

- L is the Laplace operator, which measures the smooth of the function on manifold
- On Graph, L is Laplace matrix

#### Global vs Local

- Global method : ISOMAP
- Local method : LLE, LE
- Global method can keep more informations of data
- But large amount of computation

### Out of sample problem

- LE and LLE can not applied on new samples.
- Use linear projection:  $y = \mathbf{p}^T \mathbf{x}$
- LE $\Rightarrow$  LPP:  $XLX^T$ **p** =  $\lambda XDX^T$ **p**
- LLE  $\Rightarrow$  NPE :  $XMX^T$ **p** =  $\lambda XX^T$ **p**
- Projection Matrix  $P = [\mathbf{p}_1, \dots, \mathbf{p}_d]$
- Given a new sample  $\mathbf{y}$ , we can project it to low-dim space  $\mathbf{z} = P^{\mathsf{T}}\mathbf{y}$

## **Vector Field based Dimensionality Reduction**

#### Parallel Vector Field Embedding

The goal to find a map  $F = (f_1, \dots, f_d) : \mathcal{M} \subset \mathbb{R}^n \to \mathbb{R}^d$ 

- F is a local isometry
- dF is orthonormal
- $df_i$  is parallel vector fields  $\Rightarrow \nabla df_i = 0$

#### Steps:

1. 
$$E(V) = \int_{\mathcal{M}} ||\nabla V||^2 dx$$
, s.t.  $\int_{\mathcal{M}} ||V||^2 = 1$ 

2. 
$$\min \Phi(f) = \int_{\mathcal{M}} \|\nabla f - V\|^2 dx$$

A new perspective for manifold learning

- 1. Manifold
- 2. Manifold based Dimensionality Reduction
  - 2.1 Principal Component Analysis
  - 2.2 Multidimensional scaling
  - 2.3 ISOMAP
  - 2.4 Local Linear Embedding
  - 2.5 Laplacian Eigenmaps
  - 2.6 Vector Field based Dimensionality Reduction
- 3. Manifold Regularization: Semi-Supervised Setting

#### Manifold Regularization

Measured (labeled) points: discriminant structure

$$\min \sum_{i=1}^k (y_i - f(\mathbf{z}_i))^2$$

Unmeasured (unlabeled) points: geometrical structure

$$\min \sum_{i,j} (f(\mathbf{x}_i) - f(\mathbf{x}_j))^2 S_{ij}$$

$$\min_{f} \sum_{i=1}^{k} (y_i - f(\mathbf{z}_i))^2 + \frac{\lambda}{2} \sum_{i,j}^{m} (f(\mathbf{x}_i) - f(\mathbf{x}_j))^2 S_{ij}$$

#### Laplacian Regularized Least Square

• Linear objective function

$$\min_{\mathbf{w}} \sum_{i=1}^{k} (y_i - \mathbf{w}^\mathsf{T} \mathbf{z}_i) + \frac{\lambda_1}{2} \sum_{i,j=1}^{m} (\mathbf{w}^\mathsf{T} \mathbf{x}_i - \mathbf{w}^\mathsf{T} \mathbf{x}_j)^2 S_{ij} + \lambda_2 ||\mathbf{w}||$$

Solution

$$\widehat{\mathbf{w}} = \left( ZZ^{\mathsf{T}} + \lambda_1 X L X^{\mathsf{T}} + \lambda_2 I \right)^{-1} Z \mathbf{y}$$

- $Z = (\mathbf{z}_1, \dots, \mathbf{z}_k)$ : labeled points
- $X = (\mathbf{x}_1, \dots, \mathbf{x}_m)$ : all points

#### Parallel Field Regularization

arg min 
$$E(f, V) = \frac{1}{m} \sum_{i=1}^{m} R_0(\mathbf{x}_i, y_i, f) + \lambda_1 R_1(f, V) + \lambda_2 R_2(V)$$

#### Where

- $R_1(f, V) = \int_M \|\nabla f V\|^2$ ,  $R_2(V) = \int_M \|\nabla V\|^2$
- Low cost of estimation.
- Insensitive to noise.
